Progress & Contribution

Contributor	User Story	Task
Nurjahan Ahmed Shiah	US-D.1 US-A.1 US-F.3-US-F.4 US-F.1 US-G.1 (enhancements)	Implemented feature development and full production deployment for StudySynq. > Deployed the entire platform to production, standing up the FastAPI microservices backend on Render and the Next.js frontend on Vercel. > On the feature side, I rebuilt the dashboard view to give users a clearer, more functional overview of their activity. > Added a Reddit/Discord-style campus feed so students can post and engage socially within their groups. > Implemented a full friend request system with the ability to send, accept, and manage connections, including block/unblock functionality. > also built out course management on the admin side, adding a course request system so course data can be reviewed and approved, and extracted and seeded 128 York University courses from the official course catalogue so admins have a complete, accurate course list to work with going forward.
Uzma Alam	US-A.5, US-G.3, US-G.1	Implemented the System Health Dashboard, an admin accessible diagnostic page showing the live health status of every microservice in the StudySynq platform. The backend includes a GET /health/services endpoint for the API gateway which gets the status of all the microservices simultaneously and provides their status, HTTP code, and required time to respond to the request in millisecond. The health page on the frontend displays the full summary strip. The resource page makes use of the feature AI Resource Q&A dubbed "Ask your library." The endpoint accepts the user questions in natural language, pulls the metadata for the resources related to the group of resources from the PostgreSQL database, and forms context based on the information from the names, types of the resource, and their upload dates. The prompt is sent through the Groq API. The AI study matchmaking summary features live on the recommendation page. It generates a brief rationale on why each group recommended is the right one for you, which depends on the course overlap score and activity of users involved. This response is produced by means of using the Groq API.
Ahmed (Saaram) Mustafa	M4/M5 (US-F.2, US-F.6, + notification refinements)	Moderation Console (US-F.2): Built an admin-only moderation console (/admin/moderation) in the admin-service, with RBAC enforced through the API gateway. Gives admins a platform-wide view across groups, resources, announcements, and study sessions (not scoped to their own memberships), with soft-delete moderation so content is removed without destroying data, plus an audit log of every action and the ability to select a past deletion and revert it. Added idempotent startup migrations so the moderation columns survive schema drift. Refined the revert flow to a morphing in-tab confirmation - the button turns into a red "Confirm" in the same spot on the first click instead of firing a native browser popup. Platform Analytics (US-F.6): Built an admin-only analytics overview (/admin/analytics) aggregating live PostgreSQL stats: summary cards (total/active users and groups, sessions this week, uploaded resources), most-active courses and groups tables with proportional activity bars, and a recent-activity feed. Made the rows clickable - group rows open the group page, course rows open the catalogue - and non-admins are

		redirected. Connected notifications to new services: Wired notifications into the services that were still silent. Added a group_activity category and hooked the full group member lifecycle (join/leave notify leaders; removal, role change, and ownership transfer notify the affected member); resources-service now fans out to the whole group on a new upload, and sessions-service notifies the session creator on RSVP. Every call is wrapped so a notification failure can't break the underlying action. New "Campus feed" preference: Added a user-toggable social notification category (default ON) so social-feed notifications - post comments, friend requests, and accepts - now honor a per-user toggle, wired through the shared models/schemas/helpers and surfaced on the preferences page. Testing: Added curl integration suites - tests/curl/notif-triggers (5 checks) and tests/curl/social-pref (7 checks) - covering the new notification triggers and preference enforcement, with retry helpers for the auth-service signup rate limiting.
Muhammad Fahad Sohail	Group Detail Hub & Calendar View (US-B.5 / US-C.2)	Implemented the Sessions tab on the group detail page (/groups/[id]), replacing the previous placeholder link with a fully integrated calendar view. The calendar (GroupSessionsCalendar) uses the existing useGroupSessions hook to display live session data for the selected group. The calendar supports both Month and Week views with a toggle. Sessions are displayed as colour-coded day chips to indicate upcoming, cancelled, and past sessions. On days with multiple sessions, the calendar limits the number of visible chips and shows an overflow indicator. Selecting a session opens its details page, allowing users to continue into the existing RSVP workflow. This completes the Group Detail Hub (US-B.5), with the Overview, Announcements, Tasks, Sessions, Resources, and Members tabs all backed by live data. It also completes the Calendar View (US-C.2) by providing a group-specific calendar that complements the global /sessions page introduced in Check-in 2.
Nusayba Hossain	US-G.4 and US-B.4	US-G.4 - AI Announcement Drafting Assistant: Added an AI-powered announcement helper that lets group leaders improve rough announcement drafts into clearer, professional messages before posting. Added loading, error handling, editable AI output, and cleanup for repeated titles/formatting. US-B.4 - Group Leader Management Console: Added member management controls for group leaders, including viewing the roster, adding members by email, promoting/transferring leadership, demoting members, removing members, and enforcing proper permission restrictions.
Ali Shandhor	US-D.2, US-E.4, US-F.5	US-D.2 - Resource Library: Built a group resource library with file categories, search, filters, and download links using live backend data. US-E.4 - Activity Feed: Implemented a chronological group timeline showing joins, sessions, uploads, and announcements. US-F.5 - Group Recommendations: Added group recommendations feature with match scores and shared-course explanations. Admin Portal Fixes: Fixed admin portal bugs and improved the UI for better navigation, layout, and usability.

The delta of progress between check in 03 and check in 02

Between Check-In 2 and Check-In 3, StudySynq moved from a functionally complete but locally-run system into a deployed, feature-rich platform with real AI integration, admin oversight, and social depth.

First, AI capabilities expanded significantly: an AI-powered "Ask your library" Q&A feature was added, and the recommendation engine was enriched with generated rationale text. An AI announcement-drafting assistant was also introduced, and Groq-based summaries continued to be surfaced where Check-in 2 only had a single AI summarizer, Check-In 3 has AI woven through resources, announcements, and recommendations.

Second, admin and moderation tooling grew from basic to comprehensive: a full moderation console was built with soft-delete, audit logging, and revert capability, along with a platform-wide analytics dashboard. Course request management was added, a complete 128-course catalogue was seeded, and broader admin UI bugs were fixed.

Third, the social and organizational layer of the app rounded out: a campus feed and friend request system were shipped from the user-requirements, group leader management controls were added, the Group Detail Hub was completed with a group-specific calendar view (finishing US-B.5 and US-C.2), and a resource library, activity feed, and group recommendations feature were introduced - closing out several user stories that were only partially built before.

Alongside new features, the team also went back and connected previously-siloed systems: notifications were wired into services that had stayed silent since check-in 02 (group membership changes, new uploads, RSVPs), and a user-toggleable campus feed notification preference was added, reflecting a shift from "build the feature" to "make features talk to each other properly." A system health dashboard also gave the team, for the first time, live visibility into the status of all microservices in production.

Overall, where check-in 02 was about making the system correct and secure, CI3 is about making it live, intelligent, and complete - deployed to real infrastructure, backed by AI throughout, and with nearly every planned user story now implemented.
